

std::getline, File I/O

ITP 165 – Fall 2015

Week 8, Lecture 1

Problem: Input and Multiple Words

- Remember in Mad Libs, we couldn't accept multiple word phrases.
- For example, if I run this code:

```
std::cout << "Enter a city: ";  
std::string city;  
std::cin >> city;  
std::cout << "You entered " << city << std::endl;
```
- If I type in "Los Angeles", what happens?

Problem: Input and Multiple Words

A screenshot of a Windows command prompt window titled "C:\Windows\system32\cmd.exe". The window has a black background with white text. The text displayed is: "Enter a city: Los Angeles", "You entered Los", and "Press any key to continue . . . _". The program appears to have read only the first word of the input "Los Angeles".

```
C:\Windows\system32\cmd.exe
Enter a city: Los Angeles
You entered Los
Press any key to continue . . . _
```

- It only accepted the first word, because by default `std::cin` stops at the first whitespace (space, tab, or enter)

Problem: Input and Multiple Words

- We want it instead to work like this!

A screenshot of a Windows command prompt window. The title bar shows the path "C:\Windows\system32\cmd.exe". The window contains the following text:

```
Enter a city: Los Angeles  
You entered Los Angeles  
Press any key to continue . . . _
```

Solution: `std::getline`

- In the `<string>` library, there is a function called `std::getline`
- `std::getline` allows you to get an entire line of input (so it doesn't stop until an enter)
- `std::getline` takes two parameters:
 - The input stream you want to grab the line from (what's an input stream?!)
 - The string that you want to store the line in

What is a stream?

- A **stream** is just another word for something that we will either get text input from, or write text output to
- So `std::cout` is an output stream that writes output to the console
- `std::cin` is an input stream that reads input from the console
- (As we'll see, there are potentially other input and output streams!)

std::getline in action

- So going to our previous example, we can use the std::getline function to grab the whole line:

```
std::cout << "Enter a city: ";  
std::string city;  
// std::getline takes two parameters:  
//      - the input stream  
//      - the string to store the line in  
std::getline(std::cin, city);  
std::cout << "You entered " << city << std::endl;
```

cin and getline not playing well

- If you do a `std::cin` and immediately follow it by a `std::getline` from `cin`, your `std::getline` will get ignored:

```
std::cout << "Enter number: ";  
int num = 0;  
std::cin >> num;
```

```
std::cout << "Enter a line: ";  
std::string line;  
std::getline(std::cin, line);
```

WHY
IGNORE
WHAT RETURN

```
std::cout << num << ", " << line << std::endl;
```

Cin/getline not playing well

- It skips over the getline 😞

A screenshot of a Windows command prompt window titled "C:\Windows\system32\cmd.exe". The window has a black background and white text. The text displayed is:
Enter number: 5
Enter a line: 5,
Press any key to continue . . . _
The cursor is positioned at the end of the third line. The window has standard Windows window controls (minimize, maximize, close) in the top right corner.

Cin/getline not playing well

- Add a `std::cin.ignore()` call:

```
std::cout << "Enter number: ";
```

```
int num = 0;
```

```
std::cin >> num;
```

```
std::cout << "Enter a line: ";
```

```
std::string line;
```

```
// NEED THIS IGNORE TO WORK
```

```
std::cin.ignore();
```

```
std::getline(std::cin, line);
```

```
std::cout << num << ", " << line << std::endl;
```

Cin/getline problem fixed!

A screenshot of a Windows command prompt window. The title bar shows the path "C:\Windows\system32\cmd.exe". The window contains the following text:

```
Enter number: 5  
Enter a line: Hello!  
5,Hello!  
Press any key to continue . . .
```

File Input/Output

- So far, we've only talked about Console Input/Output (I/O)...
- But what about a program like...

- It needs to read and write to files...we can do this with I/O streams that are specific to files
- So instead of cin/cout, we'll use different streams

A new library: `fstream`

- The `<fstream>` library handles streams for file input and output
- One big difference when using file streams is that unlike `cin/cout`, you have to declare a file stream before you use it
- This is because the file stream needs to know which file it's reading in or writing to!

Example: File output

```
#include <fstream>
```

```
int main()
```

```
{
```

```
    // Open the file for output
```

```
    std::ofstream fileStream("output.txt");
```

```
    // Write to the file output stream we declared
```

```
    fileStream << "Hello, World!";
```

```
    return 0;
```

```
}
```

Example: File output

- If we run this program, we won't see any output to the console:

Example: File output

- But if we find the file named “output.txt”, it will have the output!

Declaring a File Output Stream

- The syntax for this looks a little weird:

```
std::ofstream fileStream("output.txt");
```

- “ofstream” stands for “output file stream”
- The reason why it looks like this – we are actually instantiating an instance of the `std::ofstream` class (also called **constructing** the object)!

Constructing an Object – Syntax

The class we're constructing
(in this case std::ofstream)

End of statement

```
std::ofstream fileStream("output.txt");
```

What we want to name
the new object we're
constructing

Parameters to send to this
new object, in parenthesis
(in this case, the name of
the file we're writing to)

Writing to this new stream object

- To write output to this new file output stream object, it looks pretty much like a cout:

```
// Write to the file output stream we declared  
fileStream << "Hello, World!";
```

Full Example, One More Time

```
#include <fstream>
```

```
int main()
```

```
{
```

```
    // Open the file for output
```

```
    std::ofstream fileStream("output.txt");
```

```
    // Write to the file output stream we declared
```

```
    fileStream << "Hello, World!";
```

```
    return 0;
```

```
}
```

File Output Caveat

- By default, if a file already exists by the name we specify, it will be overwritten!
- So in our case, if we already have a file named “output.txt”, we will lose all of its old contents
- There’s no warning, so be careful not to open a file you don’t want to lose!
- (So don’t do this):
`std::ofstream oops("myLifesWork.cpp");`

Constructing a File Input Stream

- It looks very similar to file output...

```
// Open "numbers.txt" for input  
// Name this object fileInput  
std::ifstream fileInput("numbers.txt");
```

- Only difference is we used an “ifstream” (input file stream) instead of an “ofstream” (output file stream)

Reading from a File Input Stream

- Suppose I have a file called numbers.txt that has two numbers in it:

5

10

- Since they're numbers, I could use the input stream much like I'd use cin...

Reading from a File Input Stream - Example

```
#include <fstream>
#include <iostream>

int main() {
    // Open the file "numbers.txt" for input
    std::ifstream fileInput("numbers.txt");

    int num1 = 0;
    int num2 = 0;

    fileInput >> num1;
    fileInput >> num2;

    std::cout << num1 << std::endl;
    std::cout << num2 << std::endl;

    return 0;
}
```

Reading from a File Input Stream - Example

A screenshot of a Windows command prompt window. The title bar shows the path 'C:\Windows\system32\cmd.exe'. The window has a black background with white text. The text displayed is: '5', '10', and 'Press any key to continue . . .'. The window has standard Windows window controls (minimize, maximize, close) in the top right corner and a vertical scrollbar on the right side.

```
C:\Windows\system32\cmd.exe
5
10
Press any key to continue . . .
```

- So this works, but there are major problems with the code!

Reading from a File Input Stream - Caveats

- To make sure our code works properly when using file input, there are two issues that we have to confront:
 1. What if the file we try to open doesn't exist?
 2. How do we know when we've read in the whole file?

The `is_open` member function

- `std::ifstream` has a member function called `is_open` that tells us whether or not the file is open
- `is_open` –
 - Takes no parameters
 - Returns a `bool` – true if the file is open, false if not

is_open in action

```
#include <fstream>
#include <iostream>

int main() {
    // Open the file "randomfile.txt" for input
    std::ifstream fileInput("randomfile.txt");

    if (fileInput.is_open()) {
        // TODO: Do stuff with the file
    }
    else {
        std::cout << "Error: File not found :(" << std::endl;
    }

    return 0;
}
```

is_open in action

- So if randomfile.txt doesn't exist:

The eof member function

- The eof member function tells us when we've reached the EOF (End of File)
- eof –
 - Takes no parameters
 - Returns a **bool** – true if we're at the end of the file, false if not

Numbers, Revisited

```
#include <fstream>
#include <iostream>

int main() {
    // Open the file "numbers.txt" for input
    std::ifstream fileInput("numbers.txt");

    if (fileInput.is_open()) {
        // Continue looping as long as not at EOF!
        while (fileInput.eof() != true) {
            int num;
            fileInput >> num;
            std::cout << num << std::endl;
        }
    }
    else {
        std::cout << "Error: File not found :(" << std::endl;
    }

    return 0;
}
```

Numbers, Revisited

- So if numbers.txt has:

5

10

15

20

25

A screenshot of a Windows command prompt window. The title bar shows the path "C:\Windows\system32\cmd.exe". The window has a black background with white text. The text displayed is:

```
5
10
15
20
25
Press any key to continue . . . _
```

- Just like with `std::cin`, I can use `std::getline` on file input streams
- For example, suppose I have a file called `story.txt` with the following:

In West Philadelphia, born and raised
on the playground was where I spent
most of my days. Chillin' out maxin'
relaxin' all cool, and all shooting
some b-ball outside of the school.

- I could write a program that reads in each line, and writes it back to `cout`...

File Input and std::getline in action

```
#include <fstream>
#include <iostream>
#include <string>

int main() {
    // Open the file "story.txt" for input
    std::ifstream fileInput("story.txt");

    if (fileInput.is_open()){
        // Continue looping as long as not at EOF!
        while (fileInput.eof() != true) {
            // Use std::getline to grab a whole line
            std::string line;
            std::getline(fileInput, line);
            std::cout << line << std::endl;
        }
    }
    else {
        std::cout << "Error: File not found :(" << std::endl;
    }

    return 0;
}
```

File Input and std::getline in action

A screenshot of a Windows command prompt window. The title bar shows the path "C:\Windows\system32\cmd.exe". The window contains the following text:

```
In West Philadelphia, born and raised  
on the playground was where I spent  
most of my days. Chillin' out maxin'  
relaxin' all cool, and all shooting  
some b-ball outside of the school.  
Press any key to continue . . . _
```

Lab Practical #13
